

# Package ‘icalutils’

May 27, 2024

**Type** Package

**Title** Read, Process and Create iCalendar Data and Files

**Version** 0.2-0

**Date** 2023-12-21

**Maintainer** Enrico Schumann <es@enricoschumann.net>

**Description** Utilities for handling iCalendar data, in particular reading and creating/writing iCalendar files. The package is written in pure R, with no dependencies (package 'base64enc' is only needed if calendar files have attachments). The package maps iCalendar dates and date-times to R's native 'Date' and 'POSIXct' classes. Recurrence rules for repeated items (such as birthdays) can be expanded into actual occurrence sets. Timezones are supported.

**License** GPL-3

**URL** <http://enricoschumann.net/R/packages/icalutils> ,  
<https://git.sr.ht/~enricoschumann/icalutils> ,  
<https://github.com/enricoschumann/icalutils>

**Suggests** base64enc, tinytest

**NeedsCompilation** no

**Author** Enrico Schumann [aut, cre] (<<https://orcid.org/0000-0001-7601-6576>>),  
Unicode, Inc. [dct, cph]

 icalutils

*Read and Create iCalendar Data*

---

## Description

Read and create iCalendar data

## Usage

```
read_icalendar(file, strict.eol = TRUE, use.OlsonNames = TRUE,
               uid.names = FALSE, keep.source = TRUE,
               components = c("VEVENT", "VTODO", "VJOURNAL",
                              "VFREEBUSY", "VTIMEZONE"),
               ...)
```

```
## S3 method for class 'icalendar'
as.data.frame(x, row.names = NULL, optional = FALSE,
              adjust.allday = TRUE,
              recur.expand = FALSE,
              recur.until = NULL,
              recur.count = NULL,
              use.OlsonNames = TRUE,
              all.timestamps.POSIXct = TRUE,
              all.timestamps.Date = FALSE,
              timestamps.tz = "",
              components = c("VEVENT", "VTODO"),
              ...)
```

```
rrule(dtstart, dtend, freq,
      until = NULL, count = NULL,
      interval = 1,
      bysecond = NULL, byminute = NULL, byhour = NULL,
      byday = NULL, bymonthday = NULL, byyearday = NULL,
      byweekno = NULL, bymonth = NULL, bysetpos = NULL,
      wkst = NULL, rdate = NULL, exdate = NULL, text = NULL)
```

```
vevent(dtstart, summary, dtend = NULL,
       all.day = inherits(dtstart, "Date"),
       description = NULL, uid = NULL, categories = NULL,
       ...,
       vcalendar = TRUE, file, fold = TRUE)
```

```
to_vevent(x, ...)
```

```
save_attachments(file, out.dir, strict.eol = TRUE)
```

**Arguments**

|                                     |   |
|-------------------------------------|---|
| <code>file</code>                   | character. The file to be read ( <code>read_icalendar</code> , <code>save_attachments</code> ) or written ( <code>vevent</code> ).  |
| <code>out.dir</code>                | character: the directory where to store attachments   |
| <code>strict.eol</code>             | logical. RFC 5545 says that the end of a line should be signalled by CRLF, and when <code>strict.eol</code> is TRUE, such line ends are required. (This also means that when long lines are unfolded, the function looks for CRLF followed by a space character.) iCalendar files that use a simple LF may be read with <code>strict.eol</code> set to FALSE. |
| <code>adjust.allday</code>          | logical. If TRUE, the end day is moved one day back. If an all-day event ends on a given day, its end is stored as the next day in the icalendar format.  |
| <code>recur.expand</code>           | logical   |
| <code>recur.until</code>            | a date or datetime  |
| <code>recur.count</code>            | an integer  |
| <code>use.OlsonNames</code>         | logical. Map timezone names in file to names returned by <a href="#">OlsonNames?</a>  |
| <code>uid.names</code>              | logical: use UID values as names for the resulting list? Careful with Outlook: UIDs are often insanely long.  |
| <code>all.timestamps.POSIXct</code> | logical. To recover the original Date, use <code>as.Date(..., tz = "&lt;tz&gt;")</code> .   |
| <code>all.timestamps.Date</code>    | logical   |
| <code>timestamps.tz</code>          | character. Applies only if <code>return.class</code> is <code>data.frame</code> . This is used for local time: timestamps that have no timezone information attached. Default is "", which means to use the current timezone.   |
| <code>...</code>                    | additional arguments  |
| <code>x</code>                      | a list with class attribute <code>vevent</code> or, for <code>to_event</code> an object for which a coercion method exists  |
| <code>row.names</code>              | see <a href="#">as.data.frame</a>   |
| <code>optional</code>               | see <a href="#">as.data.frame</a>   |
| <code>dtstart</code>                | <a href="#">Date</a> or <a href="#">POSIXct</a>   |
| <code>dtend</code>                  | <a href="#">Date</a> or <a href="#">POSIXct</a>   |
| <code>freq</code>                   | a character string: SECONDLY, MINUTELY, HOURLY, DAILY, WEEKLY, MONTHLY, or YEARLY   |
| <code>until</code>                  | <a href="#">Date</a> or <a href="#">POSIXct</a>   |
| <code>count</code>                  | integer   |
| <code>interval</code>               | integer. Default is 1.  |
| <code>bysecond</code>               | a vector of integers between 0 and 60 (though 60 will be changed to 59, to comply with the POSIX standard)  |
| <code>byminute</code>               | a vector of integers  |
| <code>byhour</code>                 | a vector of integers  |

|             |   |
|-------------|---|
| byday       | The weekdays (Monday, Tuesday, ...) on which an event takes place. Takes either a vector of two-letter weekday abbreviations (mo, tu, ...), or a list of two vectors. |
| bymonthday  | a vector of integers  |
| byyearday   | a vector of integers  |
| byweekno    | a vector of integers  |
| bymonth     | a vector of integers  |
| bysetpos    | a vector of integers  |
| wkst        | character   |
| rdate       | <a href="#">Date</a> or <a href="#">POSIXct</a>   |
| exdate      | <a href="#">Date</a> or <a href="#">POSIXct</a>   |
| text        | the text of the RRULE as used in an iCalendar file  |
| keep.source | logical   |
| components  | a character vector  |
| summary     | character   |
| description | character   |
| uid         | character. If NULL, a UID is generated as suggest at <a href="https://www.jwz.org/doc/mid.html">https://www.jwz.org/doc/mid.html</a> .                                |
| all.day     | logical   |
| fold        | logical. If TRUE (the default), long lines are wrapped as described in RFC 5545, section 3.1.   |
| vcalendar   | logical. If TRUE, the VEVENT component is wrapped into a VCALENDAR, i.e. is made into an iCalendar object   |
| categories  | a character vector of keywords  |

## Details

`read_icalendar` reads a file and returns an object of class `icalendar`, which is a list of lists: each of these lists comprises one component (e.g. an event) of the `icalendar`.

The `as.data.frame` method returns a `data.frame` of a selection of properties of the events; see Value section below.

### Terminology:

An iCalendar stream (typically, a file) consist of one or more iCalendar objects. Each iCalendar object has some properties (such as the version) and one or more components, such as events, TODOs or journal entries. (This implies that there cannot be empty iCalendar objects.) These components are again composed of properties, such as 'summary'. A property may have parameters: a 'summary', for instance, may have a parameter that tells its 'language'.

### Dates and times:

iCalendar objects have three ways to describe timestamps: dates, datetimes with timezone information (which includes UTC times) and datetimes without timezone information. The functions in package `icalutils` map dates to [Date](#) and datetimes to [POSIXct](#). For times without timezones, [POSIXct](#) with timezone UTC is used, and an attribute "localtime" with value TRUE is attached.

**All-day events:**

The iCalendar specification does not detail how to treat all-day events. Two implementations seem widespread: i) events on a single day define only DTSTART, but no end; ii) DTEND is set to the date after the final day of the event. For instance, an event that lasts from August, 1 to August, 3 has DTSTART of August, 1, and DTEND at August, 4 (as in August, 4, 00:00:00). If `adjust.allday` is TRUE (the default), the end will be set to August, 3 (i.e. DTEND becomes inclusive).

**Timezones:**

Timezone names, which include specific names when daylight-saving time is in effect, are not portable and may vary between systems. Thus, the iCalendar specification requires that timezone information (i.e. a mapping from a local time to a GMT offset) must be included in the file, as components of type VTIMEZONE.

In the current version of **icalutils**, information in such VTIMEZONE components is not used. Instead, **icalutils** uses R's (very good) timezone support (see [timezones](#)) and maps datetimes with a timezone parameter to the timezone with the same name in the Olson database. This clean and transparent approach will not work on Windows (of course not). Thus, Windows timezone names (such as the infamous *Romance time* for Paris) are mapped to Olson names via data provided by the Unicode consortium. See References.

**Value**

For `read_icalendar`, a [list](#) of lists: one list for every component of the iCalendar object. If coerced to a `data.frame`, the following columns are present. Additional columns may be added later; so columns should always be addressed by name, not by position.

|                          |                    |
|--------------------------|--------------------|
| <code>uid</code>         | field value        |
| <code>summary</code>     | field value        |
| <code>description</code> | field value, or NA |
| <code>location</code>    | field value, or NA |
| <code>start</code>       | field value        |
| <code>end</code>         | field value        |
| <code>all.day</code>     | logical            |
| <code>recurring</code>   | logical            |

Enrico Schumann

**References**

For the iCalendar standard see RFC 5545 <https://tools.ietf.org/html/rfc5545>. Additional RFCs, such as 7986, may become relevant in future versions.

The mappings from Windows timezone names to Olson names are taken from the Unicode Common Locale Data Repository (<http://cldr.unicode.org/>).

**Examples**

```
read_vevent("calendar.ics")

rrule(dtstart = as.Date("2019-01-01"),
      dtend = as.Date("2019-01-05"),
      freq = "yearly", count = 5)
## $text
## [1] "FREQ=yearly;COUNT=5;INTERVAL=1"
##
## $recurrence_set
##      DTSTART      DTEND
## 1 2019-01-01 2019-01-05
## 2 2020-01-01 2020-01-05
## 3 2021-01-01 2021-01-05
## 4 2022-01-01 2022-01-05
## 5 2023-01-01 2023-01-05
```
